The Right Wine and Its Health Implications

Supplementary Note — Revised Edition, April 2026

Two substantive additions in the final revised edition of *The Right Wine and Its Health Implications* further strengthen its argument and scope. The new section, "The Color Question" (Part III, Section 8), integrates white wine and champagne into the health-relevant register, demonstrating that the criteria established for the ancestral product — low residual sugar, low pH, minimal intervention, meal integration, moderate alcohol — are color-blind and always were. The section draws on UK Biobank data and introduces Ángel Rodríguez of Martínsancho as a third pre-theoretical confirmation, parallel to Jefferson and Fernández, with direct biochemical evidence and historical continuity.

A new paragraph in Part IV, Section 1 reframes the ACC.26 UK Biobank study, showing that the Euro-centric weighting of the UK retail supply chain functions as an inadvertent partial stratification. The 21% cardiovascular mortality advantage observed is not a finding about wine as an undifferentiated category, but a signal produced by a cohort already weighted toward the ancestral product. The necessary stratified study cannot be run by design; it has been partially run by accident. The result is positive, and the argument is strengthened.

These additions reinforce the work's methodological clarity and conceptual completeness, expanding its reach without introducing inconsistency. The revised edition remains fit for wider circulation and citation.
